

# Management of genome-scale data with Bioconductor

## Bioconductor Infrastructure: ExpressionSet and SummarizedExperiment

- Similar classes of objects - expressionset usually array-based experiments and summarizedexperiment usually sequencing based experiments (rows = genomic ranges)
- Expression set lives in **Biobase** library
- **GeoQuery** allows you to pull down expressionsets by name using GSE identifier. Downloads the expressionset of microarray data
- List with single element in it - access element
- Lots of metadata - **assayData**, **phenotypic data**, **experiment**, **anotations**
- First sample - column indexing
- first row or first feature - row indexing
- Index by name
- **pData** phenotypic data - information about columns of expression set
- as.numeric on factor to see how many replicates of each strain
- pData should have same # of rows as columns in the expression set
- Feature data accessible with **FData** – genes / probe sets. Gene ID, gene symbol
- Experiment data and annotation data

## Reading Microarray Raw Data: Single-Color Arrays

- loading microArray data into R: Affymetrix one-color arrays and Agilent two-color
- Affy package: parsers for reading in raw data files
- *cel* files are raw data
- *sample info* files have table describing each sample
- **pm** = perfect match probe-level intensities
- columns of probe-level data will match the rows of **pData** - each row represents a sample and column matches sample. Rownames **pData** match colnames **pm**
- Keep character which represents platform that the technology used
- Bioconductor has a package which matches gene IDs to meaningful terms
- Experiment data, sample information, third piece of information which connects us to other information which describes genes
- Last step: turn into gene-level information -> probe level. Algorithm **rma** implemented in Bioconductor to do this using quantile normalization and background correction.
- If only want gene expression data and not probe-level, you can use **justRMA** function to read and process in one shot

## Agilent two-color Arrays

- Package **limma** for two-color arrays
- Read in sample information - pairing of files to tell you what is red channel, what is green channel. Different scanners have different way of storing.
- **lima** format is described in documentation - **readTargets**
- **read.maimages** source which tells the package what imaging software was used to produce these files
- **MA.RG** stores the log ratio of red and green
- Function to look at images

## SummarizedExperiment class

- Similar to ExpressionSets but preferred for sequencing-based data
- Accomodates experiments where genomic location is important
- Most commonly used for NGS
- **assay** function to access counts
- **colData** equivalent to **pData** on ExpressionSet
- rows correspond to genes - collections of exons (GRanges list used to count RNA sequencing reads)
- **metadata** how GRanges List was constructed and from what database etc.
- **MIAME** minimal information about microarray experiment

## Importing NGS data in R

- Two main Bioconductor packages for working with NGS data:
  - **Rsamtools** - low-level functions for reading and parsing raw NGS stored in standard formats. Interface to samtools (implemented in C)
  - **GenomicAlignments** - high-level functions and classes for reading and organizing NGS data as bioconductor objects
- BAM files - compressed format of SAM. Contains information about alignment of NGS reads to reference genome. Produced by alignment software which takes: fastq files, genomic index created from reference genome.
- Alignment software is application specific - i.e. RNA-seq programs different from genomic DNA sequencing

### How to import NGS data using Rsamtools

Example from pasillaBamSubset package

```
library(pasillaBamSubset)
library(Rsamtools)

## Specifying: what and which

- Number of functions in Rsamtools take argument param which expects **ScanBamParam** specification
- Two important options:
  - what - what kind of information to extract
  - which - which ranges of alignments to extract?
- BAM files often paired with index file to quickly pull out info about reads from a particular genomic range

```
# count the number of records (reads) on chromosome 4:
gr <- GRanges("chr4", IRanges(1, s1["chr4"]))
countBam(bf, param = ScanBamParam(which=gr))
```

```
## space start end width file records nucleotides
## 1 chr4 1 1351857 1351857 untreated1_chr4.bam 204355 15326625
```

```
reads <- scanBam(BamFile(filename, yieldSize = 5)) # limit number of reads which will be extracted to
```

## Examining the output of scanBam

- **reads** object is a list of lists - outer list indexes over the ranges in the which command. Inner list contains info from the bam file - since we didn't specify what we get everything

```

## GenomicAlignments package

- Containers for storing and manipulating short genomic alignments. Counting, computing coverage, junction detection, working with nucleotide content of the alignments
- Two most important functions in **GenomicAlignments** are:
  - **readGAlignments()** - read data from BAM files
  - **summarizeOverlaps()** - simplifies counting reads in genomic ranges across one or more files

```

## Creating a count table from a BAM file

- How to count sequencing reads which fall into genomic features
- End up with summarized experiment object - count matrix with rows corresponding to genomic ranges and columns corresponding to different samples
- Mapped to DM3 genome
- If can't find transcript database you are interested in you can use the makeTranscriptDbFromGFF file function
- Files contain transcripts and exons which make up the gene

```
library(pasillaBamSubset)
library(TxDb.Dmelanogaster.UCSC.dm3.ensGene) # transcript database
txdb <- TxDb.Dmelanogaster.UCSC.dm3.ensGene
```

```
gr1 <- exonsBy(txdb, by="gene") # for each gene, pull out the exons
gr1[100] # GRangesList of exons for 100th gene
```

```

## The GEOquery package: ExpressionSets from NCBI's repository

- Institutional archives of microarrays
- NCBI example: 17k gene expression assay platforms, 90k series, 4k datasets, 2.2mil samples
- GEOMETADB - 6 GB SQLite database. Tool for local investigation of whole GEO contents
- Pull desired experiment into R session with GEOquery
- treatment and cell type are basic experimental factors (treatment vs. control)

```

library(GEOquery)

## Platform-Oriented annotation

- GPL information page at GEO - 892 pages of platforms that have been identified
- 17k different platforms
- Most popular: Affymetrix human genome - 4760 series
- Interrogate probeset information with GEO - used to record expression values
- 1007\_s\_at interrogates gene DDR1 or certain microRNA - both occupy same cytoband so it is possible that you could use this probe
- Affymetrix oligo nucleotide probes deal with probe sets - each probe set is comprised of 25 mers
- Placed in different locations so that spatial artifacts on the array may be localized to one or another probe
- Robust to local spatial artifacts
- Info about geometry of chip, locations, contents of oligonucleotides with hgu133plus2probe package
- Most Affymetrix platforms have the probe packages in Bioconductor
  - used to study CG content of oligos, identify structural artifacts of CG content on probe intensity
